Department of Epidemiological Surveillance and Intervention

EPIDEMIOLOGICAL DATA FOR LISTERIOSIS IN GREECE
2004-2016
(MANDATORY NOTIFICATION SYSTEM)

Key points

- The notification rate of listeriosis in Greece is low.
- Based on the data for the period 2004-2016:
  - The disease was more frequent in the age group ≥ 65 years old.
  - More than 50% of the notified cases were immunocompromised patients.
  - The case fatality rate was 20.4%.
  - In 2015 and 2016, an increased number of listeriosis cases was observed.

Listeriosis is a foodborne disease caused by *Listeria monocytogenes*. The case fatality rate of listeriosis is high compared to other foodborne diseases. It mainly affects pregnant women, newborns, the elderly and immunocompromised adults [1]. *Listeria* usually causes sporadic cases, however in recent years, large outbreaks of listeriosis have been identified [2-6].

Time trend

In total, 139 cases of listeriosis were reported in Greece from 2004 to 2016. The mean annual number of cases was 10.7 (standard deviation: 8.7) and the mean annual notification rate was 0.98 cases per 1,000,000 population. In 2015 and 2016, an increased number of listeriosis cases were observed (3.22 and 1.85 cases/1,000,000 population for 2015 and 2016, respectively). The number of notified cases and notification rates for the years 2004-2016 are presented in Table 1. The incidence of listeriosis by year is depicted in Graph 1.

Age and gender distribution
For the period 2004-2016, the highest mean annual notification rate of the disease regarded the age group of ≥ 65 years old (3.19/1,000,000 population) followed by the age group of 0-4 years old (1.35/1,000,000 population). During the same period, the mean annual notification rate was 1.09 cases/1,000,000 population for males and 0.84/1,000,000 population for females. The incidence of the disease by gender and age group (0-4, 5-14, 15-24, 25-44, 45-64, 65+ years) is depicted in Graph 2.

Seasonality
The mean monthly notification rate of the disease for 2004-2016 was increased during spring, with a peak in March and gradually was decreased in the following months presenting a second peak in August (Graph 3).

Geographical distribution
The geographical region of Attica had the highest mean annual notification rate for 2004-2016 (1.44/1,000,000 population), and Central Greece (0.75/1,000,000 population), Aegean islands/Crete (0.73/1,000,000 population) and Northern Greece (0.54/1,000,000 population) had the lowest.

Risk factors/Outcome
Seventy-two (51.8%) of the total listeriosis cases, were immunocompromised patients, 4 (2.9%) pregnant women and 3 (2.2%) newborns. Among cases with known outcome (n=128), 28 (20.4%) deaths were recorded.

Increase of notified cases of listeriosis, 2015 and 2016
In 2015 and 2016, 35 and 20 cases of listeriosis were reported through the mandatory notification system, indicating an increase of the notification rate. It should be noted that there were no major changes at the mandatory notification system. In the same period the distribution of listeriosis cases by age and gender did not differ from previous years. For 2015, from the 35 reported cases of listeriosis, two regarded a pregnant woman and one case was a newborn. Concerning the case fatality, 9 cases from the 31 – for which the information was available – died (29%). For 2016, from the 20 reported cases of listeriosis, one was a pregnant woman and two cases were newborns. Regarding the case fatality, 6 to 17 cases - for which the information was available – died (35.3%).

Taking into account the geographical distribution of listeriosis cases and the distribution by time, the reported cases did not seem to be associated to a single source.

Conclusion
The notification rate of listeriosis is low in Greece. The mean notification rate in the EU and EEA/EFTA countries was 4.8 cases per 1,000,000 population for the year 2015 [7]. When interpreting this difference, the surveillance systems’ probable under-reporting should be taken into account. The age distribution, the high percentage of immunocompromised people among cases, and the high case fatality are findings compatible with those of other European countries [7]. Finally, a seasonal pattern has also been documented in other European countries with an increased number of notified cases usually between May and September [7].

The reasons that led to the increase of the reported cases of listeriosis in 2015 and 2016 have been further investigated.

The observed increase has reinforced the collaboration of the involved public health authorities. The aim of the collaboration is the timely detection of cases/outbreaks of listeriosis and the protection of the immunocompromised population and pregnant women by taking the appropriate public health measures.
